

COLLAPSE AT COMPUTATION: a storey over a storey is one storey at the composed application · $\text{anchored}(\text{anchored}(D, f), g) = \text{anchored}(D, f \circ g)$ · one machine, definitionally
the loop of retrieve, accept, retrieve is algebraically a single store

grandfathering: an accepted anchor survives new evidence exactly while its index survives, and everything above it stands · drift budget: at most one anchor revision per distinct model held

guard: modifier stores must be codes as data; unrestricted modifier families saturate in one step
